Ebuka

My contribution focused on reviewing the data preparation tasks and completing the knowledge-check responses. I examined the missing-value counts in the dataset and reviewed the age-imputation output, which showed no remaining missing age values. I also reviewed how One-Hot Encoding converts the Sex and Embarked categories into numerical columns and how StandardScaler can rescale Age and Fare. In my written answers, I explained why the median can be preferable to the mean, the purpose of One-Hot Encoding, and why Decision Trees generally do not require feature scaling. These contributions supported the explanation portion of the notebook.

Cersidy

My contribution to this module focused on data ingestion, exploration, and preprocessing using Python. I successfully imported the Titanic dataset directly from a GitHub URL and leveraged Pandas to transform the CSV data into DataFrames, giving me a clearer understanding of the dataset's structure and features.From there, I applied essential data-cleaning techniques, handling missing values in both numerical and categorical columns to improve data quality. I also used Pandas' get_dummies() function to convert categorical variables into numerical representations, making the data suitable for machine learning algorithms. Finally, I implemented StandardScaler to standardize numerical features, ensuring they were on a consistent scale. Overall, this module gave me valuable hands-on experience in transforming raw data into a clean, structured, and machine-learning-ready dataset.
